Eggs are laid they are covered in a jelly outer layer for protection. Eggs hatch 6–21 days after fertilisation.

Eggs hatch and now the tadpole can now swim and feed on algae from the pond.

Young tadpoles grow bigger. They grow legs and as they grow their tails become smaller. These are now very small frogs that can eat insects and plants .

The small frogs grow into adult frogs and no longer have tails. Frogs eat insects and plants and are able to carry on the life cycle by producing more frog spawn.
